

How much light intensity does the optical module have

Overview

The brightness of an optical module is measured in lumens and indicates how much light is emitted from the projection lens when the illumination source is at peak output and displaying a white image (all DLP micromirrors are in the on position). Humans can perceive brightness at a wavelength of 380 to 780 nm. It mainly consists of optoelectronic devices (optical transmitter and optical receiver), functional circuits, and optical bores. Its main function is to convert. The four critical radiometric quantities for optical devices are the radiant flux, the radiant intensity, radiance, and irradiance. They are defined and used as follows: Radiant flux, also called optical power, is the radiant energy per unit time that is emitted, transmitted, reflected, or received. In photometry, luminous intensity is a measure of the wavelength-weighted power emitted by a light source in a particular direction per unit solid angle, based on the luminosity function, a standardized model of the sensitivity of the human eye.
